Cart to Checkout Start conversion rate

Accuracy tier T2 - ${ASSAY_BIGQUERY_PROJECT}.analytics.cart_checkout_funnel_weekly - generated 2026-08-19 10:18:13 - shared by assay demo

(!) FIXTURE DATA - these numbers come from committed synthetic fixtures, not from a warehouse. They describe a seeded random process and are not measurements.

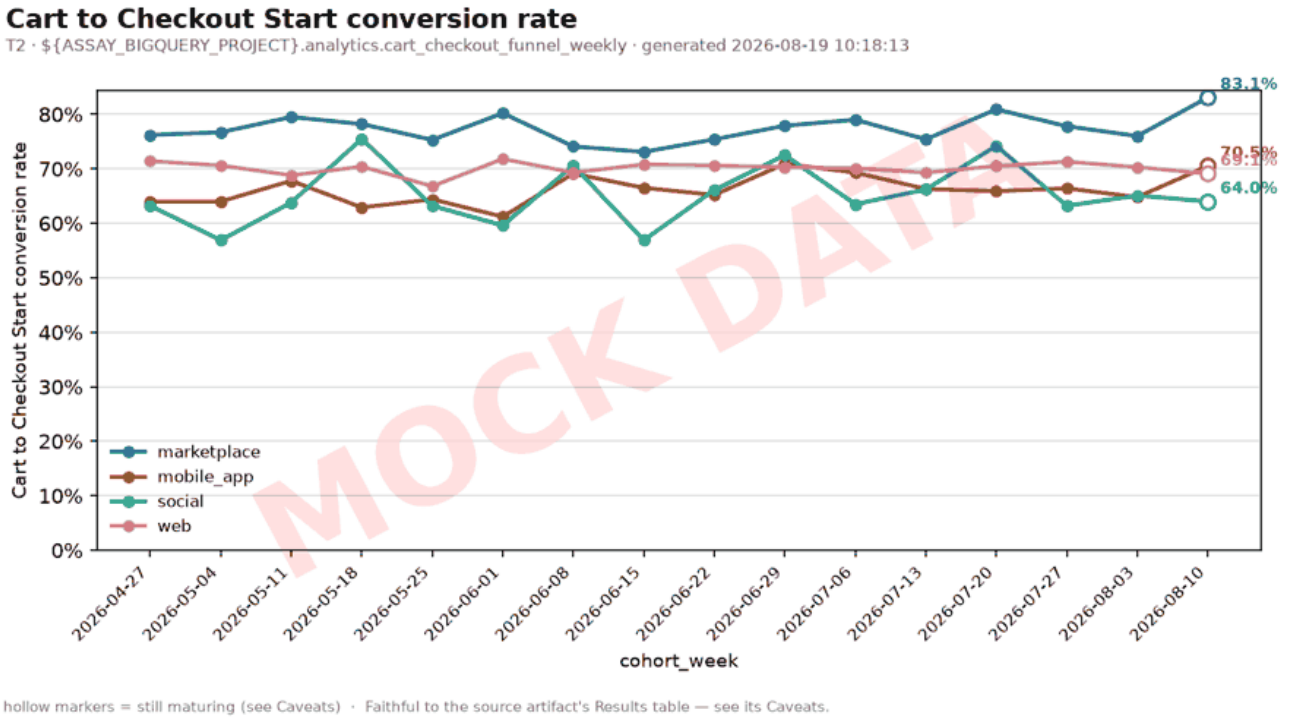

Chart type: multi_series_line - 4 series over 16 time points (<=6) -> multi-series trend line.

Results

cohort_week	channel	Cart -> Checkout	numerator	denominator

Narrative

`cart_to_checkout_start_conversion` over 2026-04-27 to 2026-08-10, split by channel, computed as SUM(numerator) / SUM(denominator) per cohort week. The headline volume is 13,199 of 19,007.

This artifact was composed by `scripts/demo.py`, which scripts a deliberately plain version of the narrative step so the compose chain is mechanically runnable. In normal use the agent writes this section against the actual question asked. The numbers are fixture-backed and describe a seeded random process, not a business.

Caveats

- Channel mix moves this number without anything changing. The channels converting between 55% and 76% means a shift in traffic mix alone will move the blended rate. Slice by channel before concluding the checkout got worse. This is the metric most often misread in the module.
- A cart is not an intent to buy. Add-to-cart is used as a bookmark, a price check, and a shipping-cost probe. A "low" rate here is partly a statement about how the cart is used, not only about checkout friction.
- Cohort anchor is cart creation. A cart created on a Sunday and returned to on Wednesday counts in Sunday's cohort week.
- Settles almost immediately (stage checkout_started, lag 0d). Mature as soon as the cohort week completes, so this is the one funnel metric that can be read fresh - do not apply the deep-stage lag to it out of caution, or you will withhold six weeks of readable data for no reason.
- Includes the retired checkout. The v1-legacy cohort sits in the first weeks of the window and converted measurably worse. Filter checkout_version=v2, or restrict the time range past the cutover, for a like-for-like trend.
- Synthetic in this template. See LINEAGE.md, fixture_data_is_synthetic.
- FIXTURE DATA: source mode is fixture_sql - ASSAY_ENGINE=sqlite - the metric's SQL is running against the committed fixture CSVs loaded into in-memory sqlite. These numbers come from committed synthetic fixtures and describe a seeded random process, not any real business. Every downstream chart, dashboard, and PDF is watermarked accordingly.
- MATURITY: 'cart_to_checkout_start_conversion' uses a per-metric maturity lag of 0d (stage_maturity[checkout_started]); cohort weeks after 2026-08-10 are withheld as not-yet-settled for stage 'checkout_started'. The lag itself is hand-authored and illustrative, NOT measured - a real deployment regenerates the stage_maturity table by measuring settle time on the spine.
- DISCONTINUITY: the 2026-04-27..2026-08-10 window crosses 2026-06-01 (delivery scan feed switched providers). Ship-to-deliver timestamps come from a different carrier feed after this date, with finer scan granularity. Delivered COUNTS are unaffected; ship-to-deliver percentiles shift by roughly half a day for feed reasons alone. Read a timing trend that crosses this date as two segments.
- CAVEAT (weekly_aggregate_is_a_narrower_interface): This view is pre-summed at cohort_week x channel x payment_method x market x category x checkout_version. It cannot express a percentile, a terminal-branch decomposition, or "did ANY of this customer's carts reach X" - those need the session spine. That narrowness is deliberate: R5 (no individual-level data) is easier to honour on a surface with no individuals on it.

Governed artifact from assay - metric `cart_to_checkout_start_conversion` - tier T2. Generated by query-metric, charted by visualize-metric. Numbers and caveats are reproduced verbatim from the source run.
